Lecture 5

Effective Abstractions (Principles, Part 1)

Example Code and Exercises

<https://github.com/eecs498-software-design/lecture>

Announcements

- Project 1 due tonight Mon Jan 26 at 11:59pm
 - Make sure all code is committed and pushed to main.
 - Detailed submission instructions in the project spec.
 - Remaining feature demos in lab this Friday Jan 30.
- Project 2
 - Released tomorrow Tue Jan 27.
 - We'll confirm groups via email and provision a new group GitHub repo.
- Lecture participation
 - Everyone gets credit for lectures 1-4. Attendance starting today in lec 5.

Video

Dimensions of Abstractions

These are all properties of the **interface** and **behavior** of the abstraction, not its implementation.

Abstractions can be qualified and assessed by:

- **Expressive Power**
- **Complexity**
- **Obscurity**
- **Depth** (Surface-to-Volume Ratio)

Much of software design is rooted in optimizing and making tradeoffs between these properties to create **effective abstractions** for a particular system.

*We might also consider **performance**. These trade-offs are often made at the language level.

Analogy – Burrito Restaurant

- **Expressive Power** What range of things you can do?

Low – The only choices are 5 premade classic burritos.

High – You can order and customize to your heart's content.

- **Complexity** How complicated is it to understand/use?

Low – They kindly walk you through all your choices and provide suggestions.

High – You must order in BNF* and must say “guac it up” if you want guacamole.

- **Obscurity** Is there hidden knowledge you might need?

Low – They give you a warning before your toppings exceed burrito capacity.

High – They silently charge you \$1 extra at checkout for each salsa after the first two.

- **Depth (Surface-to-Volume Ratio)** How much complexity does it hide?

Low – You order individual toppings and have to make the burrito yourself.

High – You can save an order as a favorite for quick ordering next time.

**Burrito-Normal Form*

Complexity and Expressive Power

- Expressive Power What range of things you can do?
- Complexity How complicated is it to understand/use?

Complexity and Expressive Power

- Expressive Power What range of things you can do?

Obscurity and Opacity

- **Obscurity** Is there hidden knowledge you might need?
 - Aim to *minimize* abstraction obscurity.
 - We may trade increased obscurity for an improvement elsewhere.

- **Opacity** Is the knowledge you don't need appropriately hidden.
 - We generally like opacity.
 - These are details you don't need – that's a benefit of abstraction!

Obscurity Tradeoffs

- Obscurity Is there hidden knowledge you might need?

- We may trade increased obscurity for an improvement elsewhere.

*"Fool! I **am** the Weasel..."*
Charlie, what have you done??

Oh, come on! How could I possibly have known that?!?

```
// REQUIRES: The vector has enough space in  
//           its underlying buffer. If you need  
//           more space, make sure to .reserve().  
// COMPLEXITY: Worst case  $O(1)$ .  
void vector<T>::push_back();
```

Higher Complexity
No Obscurity

```
// REQUIRES: Nothing.  
// If there isn't enough space, the underlying  
// buffer is reallocated with 2x capacity.  
// COMPLEXITY: Worst case  $O(N)$ , amortized  $O(1)$ .  
void vector<T>::push_back();
```

Low Complexity
Some Obscurity

Obscurity Tradeoffs

- Obscurity Is there hidden knowledge you might need?

```
// REQUIRES: Nothing.  
// If there isn't enough space, the underlying  
// buffer is reallocated with 2x capacity.  
// WARNING! May invalidate iterators on a grow.  
// COMPLEXITY: Worst case O(N), amortized O(1).  
void vector<T>::push_back(const T &val);
```

```
void add_max_to_back(const vector<T> &vec) {  
    auto it = max_element(vec.begin(), vec.end());  
    vec.push_back(*it);  
}
```

"Fool! I am the Weasel..."
Charlie, what have you done??

Oh, come on! How could I possibly have known that?!?

Depth

- Depth How much complexity does it hide?
 - Aim to *maximize* abstraction depth.
 - A deep abstraction will make your life easier.

```
// Not so Complex, Expressive, Deep
circle.config({
  color: { r, g, b },
  radius: 4,
  // other configs optional
});
```

```
// Hides mathematical complexity. How
// do you even compute a square root?
const y = Math.sqrt(x);
```

```
// Fairly shallow - but that's ok
circle.set_color(r, g, b);
circle.set_radius(r, g, b);
circle.set_outline_width(r, g, b);
```

```
// Deeper - is it better?
circle.set_color_and_radius(r, g, b, rad);
```

```
// Even deeper - is it better?
circle.set_color_and_radius_and_outline_widh(
  r, g, b, rad, t);
```

Composition (Depth as Surface-to-Volume Ratio)

- **Compose** several shallower abstractions along (mostly) **orthogonal** dimensions.
- Example: Higher-order array functions that accept a predicate.

	is_even()	is_prime()	$(x) \Rightarrow x \text{ === } 0$	...
filter()				
count_if()	count_evens()			
replace_if()				
...				

Individually, `count_evens()` is a deeper abstraction than `count_if() + is_even()`

But... consider the library of these functions holistically!

A: $n \times m$ functions

B: n functions + m predicates

A and B have equal “volume” of functionality, but B has a smaller interface surface.

Custom predicates arguably add expressive power!

- Shallow(er) pieces, deep compositions.
- Not 100% free! Complexity may move to coupling between pieces... (next time)

Low-Depth Abstractions

- Abstractions hide complexity
 - More depth = more hidden complexity
- Abstractions aren't free
 - Complexity and obscurity are never truly zero.
At a minimum, there's some cognitive overhead.
- Consider removing **low-depth abstractions**, when the benefit doesn't justify the cost.

```
class Circle {  
    private rad: number;  
    getRadius(): number { return this.rad; }  
    setRadius(rad: number): void { this.rad = rad; }  
};
```

```
class Circle {  
    private rad: number;  
    getRadius(): number { return this.radius; }  
};
```

```
class Circle {  
    readonly public rad: number;  
};
```

```
let email = "";  
email += formatSubtotalLine(order.subtotal);  
email += formatTaxLine(order.tax);  
email += formatTotalLine(order.total);
```

```
function formatSubtotalLine(subtotal: number): string {  
    return `Subtotal: ${formatCurrency(subtotal)}`;  
}
```

Case Study: Luxon Date/Time Library

```
import { DateTime } from 'luxon';

// There is so much complexity hidden away here, e.g.
// how many days per month, leap years, daylight savings time, etc.
const result = DateTime.now() // Local system time
  .setZone('America/New_York') // Map to a specific timezone
  .plus({ months: 7 }) // 7 months from now
  .setLocale('fr') // Print using a French locale
  .toLocaleString(DateTime.DATETIME_FULL);

console.log(result); // e.g., "26 août 2026 à 07:10 UTC-4"
```

Design Pattern: Facade

- The Façade pattern generally trades:
 - reduced expressive power
 - or increased obscurity
- To gain reduced complexity

Video

KISS and YAGNI

- **KISS** Keep It Simple, Stupid

People often *underestimate* the cost of complexity.

- **YAGNI** You Ain't Gonna Need It

People often *overestimate* the value of expressiveness or composability.

*But lad, this time's different.
Mrs. Puff needs this!*
